Introduction	1
Table 1.—Crude protein equivalents for 13.5 per cent moisture content	4
Table 2.—Ash equivalents for 13.5 per cent moisture content	22
Table 3.—Crude protein in wheat and flour computed from the percentages of total nitrogen found	30

INTRODUCTION

The crude protein content of wheats has become an important factor in establishing their market value, because of the general relationship existing between the crude protein content of wheat and the baking quality of the flour made from it. In some markets premiums of as much as 5 cents a bushel have been offered for each additional half of 1 per cent of crude protein contained in the wheat above an agreed percentage. Ash content also is an important factor in the marketing of flour.

In considering these factors very little attention has been given by the trade to the moisture content of the material for which specific protein and ash values are given. There is a wide variation in the moisture content of different samples of grain or flour and even in the moisture content of the same sample at different times.

The prevailing practice of reporting the crude protein and ash content on a basis of the moisture content of the sample when the determination was made is confusing to the trade because misunderstandings and irregularities are bound to occur, especially with those

not familiar with the methods of chemical determination of these factors. A uniform moisture base is needed.

For example, a crude protein content of 14.1 per cent in a moisture-free sample is equivalent to only 13.1 per cent if there is 7 per cent moisture, to 12.2 per cent at 13.5 moisture, and to 11.8 per cent when the moisture is 16.0 per cent. This apparent difference (2.3 per cent in the reported percentage) is due solely to the basis of reporting, as the material is the same.

The equivalents for crude protein and for ash (Tables 1 and 2) are computed on a basis of 13.5 per cent moisture, as a ready means of converting reported percentages to a uniform base. The 13.5 per cent base is adopted for this purpose because that is the maximum percentage of moisture allowed in flour in the enforcement of the Federal food and drugs act, and because it is close to the normal amount of moisture found in both wheat and flour in many sections of the country. Further, this base is already being used for this purpose by some laboratories.

For the reasons here stated tables are presented which give the crude protein and ash equivalents at 13.5 per cent moisture content. They should be found useful to grain buyers, grain inspectors, bakers, and to chemists in general, particularly to all cereal chemists engaged in making determinations for these factors. The tables can also be used for conversion to a moisture free base if so desired.

That the tables may be easily understood, an illustration of their use follows: If the crude protein content in a sample containing 9.0 per cent of moisture is 12 per cent, the equivalent crude protein content at 13.5 per cent moisture is found by tracing down the column headed by 12.0 per cent protein until opposite 9.0 per cent moisture content, the figure 11.4 found at that point represents the proper equivalent. The equivalent crude protein for the moisture-free base may be found by first finding the equivalent at 13.5 per cent moisture. Then find the same percentage opposite the 0.0 per cent moisture content, and directly above it in the crude protein column headings is the proper equivalent at 0.0 moisture content. In the example just cited this equivalent is 13.2 per cent.

In making up these tables the percentages of crude protein and moisture is given to tenths of 1 per cent.

The protein percentages presented in Table 1 were not calculated beyond the tenths place because if they had been so calculated the tables would have been too bulky for any practical use, and, furthermore, because hundredths of a per cent are without value in the case of this factor for the reason that the constant 5.7 used in converting nitrogen percentages to crude protein percentages is an arbitrary one. The conversion factor ranges from 5.67 to 5.70. Therefore,

the hundredths of a per cent has to do with mathematical rather than analytical accuracy.

The formula used for obtaining the crude protein and ash percentage equivalents given in Tables 1 and 2 is as follows:

M = Percentage of moisture in sample.

P_1 = Percentage of crude protein or ash for M moisture content.

P_2 = Percentage of crude protein or ash for 13.5 per cent moisture content.

To find P_2:

$$P_2 = \frac{P_1 \times (100.0 - 13.5)}{100.0 - M}$$

Example:

Let $M = 11.0$ per cent moisture.

$P_1 = 10.0$ per cent crude protein.

To find P_2 (substituting the above values in the formula):

$$P_2 = \frac{10.0 \times (100.0 - 13.5)}{100.0 - 11.0} = \frac{10.0 \times 86.5}{89.0} = \frac{865.0}{89.0} = 9.7$$

TABLE 1.—*Crude protein equivalents for 13.5 per cent moisture content*
